Revised after it
1996/1/12

Ver. 1.0 [00/11/25 12:04]
1 Introduction to cells

\[ \begin{aligned}
\text{cells:} & \quad \left\{ \begin{array}{l}
\text{primitive ideals of } U(\mathfrak{g}) \quad (\mathfrak{g} : \text{semisimple Lie algebra}) \\
\text{representation theory of finite Chevalley groups (unipotent representations)} \\
\text{modular representation theory}
\end{array} \right. \\
\text{etc.}
\end{aligned} \]

Since I am not a specialist of finite Chevalley groups or modular representation theory, I will explain properties of cells through \textit{primitive ideals of } U(\mathfrak{g}).

**Role in the theory of primitive ideals:**

\[ \mathfrak{g} : \text{a semisimple Lie algebra } / \mathbb{C} \]
\[ U(\mathfrak{g}) : \text{the enveloping algebra } \supset \mathfrak{z} : \text{center} \]
\[ \mathfrak{g} \supset \mathfrak{h} : \text{CSA, } W = W(\mathfrak{g}, \mathfrak{h}) : \text{Weyl group} \]

\[ \mathfrak{z} \overset{\sim}{\longrightarrow} U(\mathfrak{h})^W : \text{Harish-Chandra isomorphism} \]

For \( \lambda \in \mathfrak{h}^* \), \( \exists \chi_\lambda : \mathfrak{z} \rightarrow \mathbb{C} : \text{algebra hom.} \)

\[ U(\mathfrak{h})^W = S(\mathfrak{h})^W \]

\( \chi_\lambda : \text{the central character corresponding to } \lambda \): Note that \( \chi_\lambda = \chi_{w\lambda} \) \((w \in W)\).

\( L : \text{an irreducible left } U(\mathfrak{g})\)-module

\[ \text{Ann } L = \{ X \in U(\mathfrak{g}) | Xl = 0 \ (\forall l \in L) \} : \text{primitive ideal}^{1} \]

\[ \text{Ann } L \cap \mathfrak{z} = \ker \chi_\lambda \ (\exists \lambda \in \mathfrak{h}^*) \overset{\text{der}}{\leftrightarrow} \text{Ann } L \in \text{Prim}(\lambda) : \text{primitive ideals with central character } \chi_\lambda \]

\[ \text{Prim } U(\mathfrak{g}) = \coprod_{\lambda \in \mathfrak{h}^*/W} \text{Prim}(\lambda) \]

**Example 1.1** Prim(\( \rho \) \( \ni \) Ann(trivial rep.))

\[ ^{1}\text{There are several notions of primitivity in } U(\mathfrak{g}) \ (\text{cf. Dixmier [Dixmier]}). \]

\[ \begin{align*}
I & \quad : \text{maximal} \quad \Downarrow \\
\Downarrow & \quad \Downarrow \\
I & \quad : \text{completely prime} \quad \Rightarrow \quad I : \text{prime} \quad \Rightarrow \quad I : \text{semi-prime}
\end{align*} \]

\[ A \ni 1 : \text{ring} \]

(1) \( I \subset A : \text{prime ideal } \iff \left( A/I \ni \forall J_1, J_2 : \text{ideals } \neq 0 \Rightarrow J_1 \cdot J_2 \neq (0) \right) \]

(2) \( I \subset A : \text{completely prime } \iff \ A/I : \text{integral domain} \]

(3) \( I \subset A : \text{semi-prime ideal } \iff \left( A/I \ni J : \text{nilpotent ideal } \Rightarrow J = (0) \right) \]
By translation principle, \( \text{Prim}(\rho) \simeq \text{Prim}(\rho + \lambda) \forall \lambda \in P^+ (\Delta) \)

\[ \Delta = \Delta (\mathfrak{g}, \mathfrak{h}) : \text{roots} \]

\( P^+ (\Delta) : \text{dominant integral weights} \)

**Parametrization of \( \text{Prim}(\rho) \)?**

\[ w \in W \quad M_w = M (w \rho - \rho) : \text{Verma module with h.w. } w \rho - \rho \]

\[ \downarrow : \text{surjection} \]

\[ L_w = L (w \rho - \rho) : \text{its irreducible quotient} \]

**Theorem 1.2 (Duflo, 1977 [Duflo])** \( \varphi : W \ni w \mapsto \text{Ann } L_w \in \text{Prim}(\rho) \text{ is surjective.} \)

Actually Duflo proved more. He proved the theorem for general central character \( \chi_\lambda \)'s, which are possibly singular.

Classification of \( \text{Prim}(\rho) \Leftrightarrow \text{determination of fibers of } \varphi \]

\[ \varphi(w) = \varphi(w') \]

This equivalence relation defines the left cells in \( W \), i.e., \( \Gamma = \Gamma(w) = \{w' \mid \varphi(w) = \varphi(w')\} \)

is a left cell (Joseph and Vogan, 1980).\(^2\)

Write \( \sim_l \) instead of \( \sim \).

**Example 1.3** type \( A_{n-1} \), \( W \simeq \mathfrak{S}_n : \text{symmetric group of order } n \)

\[ \mathfrak{S}_n \ni w \leftrightarrow (T^L_w, T^R_w) : \text{pair of standard tableaux of the same shape} \]

Robinson-Schensted

\[ w \sim_l w' \Leftrightarrow T^L_w = T^L_{w'} \] (Barbasch-Vogan, 1982 [BVI, p.171]).\(^3\)

\[ \mathfrak{h}^* \ni \mu \mapsto \text{rk}(U(\mathfrak{g})/\text{Ann } L(\mu - \rho)) = p(\mu) : \text{Goldie rank} \]

\( P^l (\Delta) : \text{regular integral weights, } P^l (\Delta)^++ = \{\mu \in P^l (\Delta) \mid \mu : \text{dominant}\} \)

**Theorem 1.4 (Joseph, 1980 [JII, Cor. 5.12])** For \( w \in W \), \( p(\mu) \) is a polynomial on \( P^l (\Delta)^++ \). Denote this polynomial by \( p_w (\mu) : \text{Joseph’s Goldie rank polynomial} \)

**Remark.** Using the notion of “coherent family”, this theorem is more comprehensive. \( p_w (\mu) \) coincides with the character polynomial (up to scalar multiple) of the coherent family containing \( L_w \). (Joseph, 1980 [JII, Theorem 5.1]. Cf. King, 1981 [King].)

\(^2\)This is the definition of left cell \( \Gamma \) here, but historically, the left cells are defined by Lusztig by using purely algebraic structures of Coxeter groups. The equivalence of two definitions are established by Joseph and Vogan. See Theorem 1.6.

\(^3\)If \( \sim_l \) is similarly defined by using the right annihilators, then \( w \sim_l w' \Leftrightarrow T^R_w = T^R_{w'} \).

For two-sided cells, \( w \sim_{lr} w' \Leftrightarrow T^L_w = T^L_{w'} \) and \( T^R_w \) have the same shape \( \Leftrightarrow T^R_w \) and \( T^R_{w'} \) have the same shape .

\(^4\)A : a prime ring (i.e., \( 0 \) is a primitive ideal \( \nRightarrow \exists \) faithful irreducible representation)

Then \( \text{Fract}(A) \simeq \text{Mat}(n \times n, D) \) for some division ring \( D \). Define \( \text{rk}A := n. \)
$p_w(\mu)$: a harmonic polynomial on $\mathfrak{h}^*$, generates an irreducible $W$-module.

$\Gamma$: left cell $\ni w, w' \Rightarrow p_w(\mu) = p_{w'}(\mu)$ (by definition they take the same value on $\rho$ + they are proportional. See [JL, Cor.5.12])

$\Rightarrow$ Write $p_{w'}(\mu) = p_w(\mu) \quad (w \in \Gamma)$.

$\forall \sigma \in W^\vee$

$$
C_\sigma := \prod \{ \Gamma | CW_{p_\Gamma} \simeq \sigma \} \subset W
$$

$C = C_\sigma$: two-sided cell in $W$ (if $C_\sigma \neq \emptyset$)

equivalence relation $w \sim w' \iff w, w' \in \exists \mathcal{C}$

$\sigma \in W^\vee$: special representation$^6$ def. $\iff C_\sigma \neq \emptyset$

$$
dim \sigma = \#\{ \Gamma | \Gamma \subset C_\sigma : \text{left cell} \} \Rightarrow \#\text{Prim}(\rho) = \sum_{\sigma \in W^\vee : \text{special}} \dim \sigma
$$

Example 1.5 type $A_{n-1}$. $\forall \sigma \in \mathfrak{S}_n^\vee$ : special $\leftrightarrow Y_\sigma$ : Young diagram

$$
\begin{align*}
C_\sigma &= \{ w \leftrightarrow (T^L_w, T^R_w) | T^L_w \text{ has the shape } Y_\sigma \} \\
\cup \\
\Gamma &= \{ (T^L_w, T^R_w) \} : \text{for the fixed standard tableau } T^L_w
\end{align*}
$$

$\Rightarrow$ $\#\{ \Gamma | \Gamma \subset C_\sigma \} = \#\{ \text{standard tableau of the shape } Y_\sigma \} = \dim \sigma$

$$
\#\text{Prim}(\rho) = \sum_{\sigma \in \mathfrak{S}_n^\vee} \dim \sigma = \#\{ \text{involutions in } \mathfrak{S}_n \}
$$

$$
\#\{ \Gamma \subset \mathcal{C} \} = \#\{ \text{involutions } \in \mathcal{C} \} \quad ([\text{Duflo, Proposition 9}], \text{cf. } [\text{Borho, \S5.9}])
$$

Remark. The above left (or two-sided) cells can be defined by using only combinatoric properties of a Coxeter system (by Kazhdan-Lusztig [KL]). So they are defined for general Coxeter groups, not only for Weyl groups. See [BVII, Remark after Cor.2.16].

$$
\text{Char } L_w = \sum_{w' \in W} a_{w, w'} \text{ Char } M_{w'} \quad (a_{w, w'} \in \mathbb{Z})
$$

$a_{w, w'}$ is explicitly determined (Kazhdan-Lusztig conjecture). But we do not need the explicit information.

$$
a(w) := \sum_{w' \in W} a_{w, w'} w' \in CW
$$

$$
D(w) := \{ w' | a(w') \in [CW a(w)] \} = \{ w' | \text{ Ann } L_{w'} \supset \text{ Ann } L_w \}
$$

The second equality is due to Vogan [Vogan].

---

$^5$This is not empty if $\sigma$ is a special representation. See below.

$^6$Special representations are originally introduced by Lusztig ([LI, LII]). However, two different notions coincide ([BVII, Theorem 2.29]).
Here, $[S]$ means a-basal subspace\(^7\) in $\mathbb{C}W$ spanned by $S$.

**Theorem 1.6 (Joseph [Joseph], Vogan [Vogan])**

$$w' \sim_L w \iff [\mathbb{C}W a(w')] = [\mathbb{C}W a(w)]$$

For $\Gamma$ : a left cell ($w \in \Gamma$), we put\(^8\)

$$\sigma_\Gamma := \sum_{w' \in D(w)} [\mathbb{C}W a(w')] / \sum_{w'' \in D(w), w'' \not\in \Gamma} [\mathbb{C}W a(w'')] : \text{left cell representation, not irreducible in general}$$

Similarly put

$$C(w) = \{w' \mid a(w') \in [\mathbb{C}W a(w)]\}$$

**Theorem 1.7 ([BVII, Cor.2.16])**

$$w \sim_{LR} w' \iff [\mathbb{C}W a(w')W] = [\mathbb{C}W a(w)W]$$

For $C$ : a two-sided cell ($w \in C$), we put\(^9\)

$$\sigma_C := \sum_{w' \in C(w)} [\mathbb{C}W a(w')W] / \sum_{w'' \in C(w), w'' \not\in C} [\mathbb{C}W a(w'')]W : \text{two-sided cell representation}$$

As a $W \times W$-module,

$$\sigma_C = \sum_\tau \otimes \tau (\text{multiplicity free})$$

$$\mathcal{F}_C := \{\tau \in W^\vee \mid |\sigma_C : \tau \otimes \tau| = 1\} \subset W^\vee : \text{a family associated to } C$$

$\mathcal{F} = \mathcal{F}_C$ is also called two-sided cell\(^10\) in $W^\vee$.

$$W^\vee = \coprod_{c : \text{two-sided cell}} \mathcal{F}_c$$

$\forall \mathcal{F}_c$ contains exactly one special representation, i.e., $\{\text{special representations } \in W^\vee\}$ gives a complete system of representatives for families.

---

\(^7\) A subspace in $\mathbb{C}W$ is called a-basal if it has basis consisting of $a(w')$'s. See Joseph II 298p. Note that $\{a(w) \mid w \in W\}$ forms a basis of $\mathbb{C}W$. In the original version of this note, I misunderstood the definition of $D(w)$; Tanisaki kindly pointed it out.

\(^8\) The first summation in the right hand side of the next formula is surplus.

\(^9\) Here, the summation is also surplus.

\(^10\) Original definition of family is very complicated one ([Orange Book, §4.2]). However it coincides with the definition presented here (Barbasch-Vogan [BVII, Theorem 2.29], cf. [Orange Book, Theorem 5.25]).
2 Invariant for cells

We want to define an invariant for families \( \{ \mathcal{F} \} \).
The present observations are experimental ones\(^1\).

**Gyoja** (1983) \[ \text{Gyoja} : \sigma \in H_q(W)^\vee, \quad H_q(W) : \text{an Iwahori-Hecke algebra}^{12} \]

\[
L(t, \sigma) = L(t, q, \sigma) := \sum_{w \in W} \sigma(w)t^{l(w)} (l(w) : \text{length function})
\]

\[
L(t, \sigma) : \begin{cases} 
\exists \text{functional equation} \\
\text{distribution of zeros and poles}^{13} \text{ are similar to zeta functions}^{14} \text{ (congruence zeta functions on algebraic varieties).}
\end{cases}
\]

Iwahori’s suggestion \( \Rightarrow \) Take \( l'(w) \) instead of \( l(w) \);

\[
l'(w) := \left( \begin{array}{c}
\text{minimal of } m, \text{ where } w = r_1r_2 \cdots r_m, \\
(r_i : \text{reflection (not necessarily simple)})
\end{array} \right)
\]

(Cf. for type \( A \), \( \# \text{Prim}(\rho) = \# \{ \text{involutions} \} \))

**Remark.** \( W \hookrightarrow V : \) natural representation, \( V(w) := \{ v \in V \mid vw = v \} \) \( (w \in W) \).
Then \( l'(w) = \text{codim } V(w) \).

\[
\begin{align*}
\text{Gyoja-N.-Shimura} : \\
\sigma \in W^\vee, \quad W : \text{not an Iwahori-Hecke algebra, but a finite Weyl group.}
\end{align*}
\]

\[
c(\sigma, t) := \sum_{w \in W} \left( \text{trace } \sigma(w) \right)t^{l'(w)}
\]

**Does** \( c(\sigma, t) \) **classify cells?**? (\( c(\sigma, t) \) is computable!)

For types \( A_t, B_t(= C_t), G_2 : \) yes! i.e.,

\[
\sigma_1 \sim_{LR} \sigma_2 \ (\iota \in \text{Aut}(W, S)) \iff c(\sigma_1, t) = c(\sigma_2, t)
\]

(\( \sigma_1 \) and \( \sigma_2 \) belong to the same family)

For Weyl groups of the other types, some deviation occurs.

\(^{11}\)M. Sato: Every mathematician should be an experimentalist.

\(^{12}\)For a long time, \( H_q(W) \) is simply called Hecke algebra. Recently, it becomes to be called Iwahori-Hecke algebra. For this, see Introduction of [Orange Book].

\(^{13}\)In case of affine Weyl groups, poles appear. However, in this note, Weyl groups always remain finite.

\(^{14}\)Functional equation:

\[
L(t, \sigma) = \sigma(T_{w_0})t^{l(w_0)}L((-qt)^{-1}, \hat{\sigma}), \quad w_0 : \text{the longest element}, \quad \hat{\sigma}(T_w) = (-q)^{l(w)}(T_{w^{-1}})^{-1}.
\]

zeros:

\[
t = \zeta q^{-i/2m}, \quad \zeta : \text{root of unity, } \ i, m \in \mathbb{Z} \text{ s.t. } 1 \leq m \leq l(w_0), 0 \leq i/2m \leq 1.
\]
Want to avoid the deviation.
$W \sim V$: natural representation, $\{m_i\}$: exponents, $H(V) = \oplus_n H^n(V)$: harmonic polynomials
$\sigma \in W^\vee, \chi = \text{Char } \sigma$

$$\tilde{\tau}(q,y)(w) := \frac{\det(1 + yw|V)}{\det(1 + qw|V)}$$
$$\tilde{\tau}(\sigma; q, y) := \langle \chi, \tilde{\tau}(q,y) \rangle_W$$
$$= \frac{1}{\#W} \sum_{w \in W} \chi(w^{-1}) \tilde{\tau}(q,y)(w)$$
$$= \sum_{i,j} \langle S^i(V) \otimes \wedge^j(V), \chi \rangle w^i y^j$$
$$= \frac{\dim \sigma}{\prod_{i=1}^{l}(1-q^{m+1})} \sum_{n,m \geq 0} \left[ \chi : H^n(V) \otimes \bigwedge^m(V) \right] q^ny^m$$

Proposition 2.1 $l := \text{dim } V$: rank of $W$

$$\frac{\#W}{\dim \sigma} \lim_{q \to 1} \tilde{\tau}(\sigma; q, -1 + t(1 - q)) = t^l c(\sigma; t^{-1})$$

$\Longrightarrow \tilde{\tau}(\sigma; q, y)$ refines the property of $c(\sigma, t)$.

From now on, $W$ is assumed to be irreducible.

Observation 2.2 $\tilde{\tau}(\sigma; q, y)$ has many factors of the same type $(1 + qf(y))$ ($c \in \mathbb{Z}$).

Example 2.3 (Or a proposition)

$$\#(\text{family}) = 1 \Rightarrow \tilde{\tau}(\sigma; q, y) = f(q) \prod_{i=1}^{\text{rank}} (1 + q^i y)$$

$$\tilde{\tau}(\text{trivial}; q, y) = \prod_{i=1}^{l} \frac{1 + yq^{m_i}}{1 - q^{m_i+1}}$$

Example 2.4 (See §3) type $A_{l-1}: W \simeq \mathfrak{S}_l$

$$\tilde{\tau}(\chi^\lambda; q, y) = q^{n(\lambda)} \prod_{x \in \lambda} \frac{1 + q^{c(x)} y}{1 - q^{h(x)}} \lambda : \text{partition and tableau}$$

notations: (cf. Macdonald’s book [M])

$$n(\lambda) = \sum (i - 1)\lambda_i, \quad x = (i,j) \in \lambda \subset \mathbb{Z}^2, \quad c(x) = j - i, \quad h(x) = \text{hook length}$$
We put $\tau_1(\sigma; q, y) = \prod_{i=1}^{\kappa(\sigma)} (1 + q^{d_i}y)$: the largest factor of $\bar{\tau}(\sigma; q, y)$ including only the factors $(1 + q^{d_i}y)$ ($c \in \mathbb{Z}$).

**Theorem 2.5** If

1. $W$ is of type $A_l, B_l (= C_l), G_2$ or
2. $W$ is of type $D_l, F_4, E_i$ ($i = 6, 7, 8$) and $(\text{family}) \leq 3$,

then

$$\sigma_1 \sim \sigma_2 \ (\in \text{Aut}(W, S)) \Leftrightarrow \tau_1(\sigma_1; q, y) = \tau_1(\sigma_2; q, y)$$

i.e., $\sigma_1$ and $\sigma_2$ belong to the same family.

**Remark.** Even for the case $(\text{family}) \geq 5$, the above theorem is *almost* true. We can attach linear factors like $\tau_1(\sigma; q, y)$ for each $\sigma \in W^\vee$, but it is not the largest linear factor (i.e., we must choose “special” linear factors).

**Remark.** If $(\text{family}) = 3$,

$$\bar{\tau}(\sigma_1; q, y) + \bar{\tau}(\sigma_2; q, y) = f(q) \prod_{i} (1 + q^{d_i}y) \ (d_i \in \mathbb{Z})$$

for any two representations $\sigma_1, \sigma_2$ in the family.

Similar phenomena occur for the case of type $D_l$ (and $(\text{family}) \geq 5$).

The set of (computable) integers

$$(c_1, c_2, \cdots, c_{\kappa(\sigma)})$$

determines a family (or two-sided cell) in $W^\vee$ (for $W$ in the theorem).

If we overcome the deviation explained above (i.e., the case of $(\text{family}) \geq 5$), the computable invariants $(c_i)$ really classifies families (or two-sided cells) in $W^\vee$ (even for non-irreducible $W$’s).

**Problem 2.6** (1) Find a method to choose special linear factors for exceptions of the above theorem.

(2) The above consideration is an experimental one. Clarify the meaning of the invariants $(c_i)$ from the view points of the representation theory of Weyl groups or Iwahori-Hecke algebras, theory of primitive ideals, finite Chevalley groups, modular representation theory . . . .
3 Calculation of $\tau$ for type A

This section is almost borrowed from Macdonald’s book: [M].

First, let us introduce some general theory from [M, §I.2 and §I.3]. In the following, $t$ is an indeterminate and $h_r, e_r, p_r$ are coefficients;

\[ H(t) = \sum_{r\geq 0} h_r t^r \quad (h_0 = 1) \]

\[ E(t) := \frac{1}{H(-t)} = \sum_{r\geq 0} e_r t^r \]

\[ P(t) := \frac{d}{dt} \log H(t) = H'(t)/H(t) = \sum_{r\geq 0} p_r t^r \]

For a partition $\lambda = (\lambda_1, \lambda_2, \cdots)$, put

\[ h_\lambda = \prod_{i\geq 1} h_{\lambda_i}^i, \quad e_\lambda = \prod_{i\geq 1} e_{\lambda_i}^i, \quad p_\lambda = \prod_{i\geq 1} p_{\lambda_i}^i. \]

**Theorem 3.1**

\[ h_r = \sum_{|\lambda|=r} \frac{1}{z_\lambda} p_\lambda, \quad e_r = \sum_{|\lambda|=r} \frac{\varepsilon_\lambda}{z_\lambda} p_\lambda \]

Here, we used the following notation:

\[ z_\lambda := \prod_{i\geq 1} t^{m_i} m_i! \quad (\lambda = (1^{m_1} \cdot 2^{m_2} \cdot 3^{m_3} \cdots) \quad i.e., m_i = \# \{ j | \lambda_j = i \}) \]

\[ = \frac{\#(\text{conjugacy class in } S_n \text{ corresponding to } \lambda)}{n!} \quad (n = |\lambda|) \]

\[ \varepsilon_\lambda := (-1)^{|\lambda|-l(\lambda)} \]

**Theorem 3.2** Put

\[ s_\lambda := \det(h_{\lambda - i + j})_{1 \leq i,j \leq n} \quad (n \geq l(\lambda)) \]

\[ = \sum_{w \in S_n} \varepsilon(w) h_{\lambda + \delta - w \delta} \]

\[ = \det(e_{\lambda - i + j})_{1 \leq i,j \leq m} \quad (m \geq l(\lambda')) \]

Now put $n := |\lambda| (\geq l(\lambda))$ and take the character $\chi^\lambda$ of $S_n$ corresponding to $\lambda$. Then we have

\[ s_\lambda = \sum_{\mu} \frac{1}{z_\mu} \chi^\lambda(\mu)p_\mu, \]

where $\mu$ runs over all the partitions of $n$ (i.e., conjugacy classes of $S_n$).
Example 3.3 ([M, §I.2 and §I.3]) Let \( \{x_i\} \) be the set of indeterminates.

\[
H(t) := \prod_{i=1}^{n} \frac{1}{1 - x_i t}
\]

\[
\Rightarrow \begin{cases}
  h_r & : \text{complete symmetric function of degree } r \\
  e_r & : \text{elementary symmetric function of degree } r \\
  p_r & = \sum_{i=1}^{n} x_i^r
\end{cases}
\]

\[
s_\lambda = \frac{a_\lambda + \delta}{a_\delta} : \text{Schur function}
\]

\[
= \frac{\sum_{w \in S_n} \varepsilon(w) w(\lambda + \delta)}{\sum_{w \in S_n} \varepsilon(w) w(\delta)} (\delta = (n-1, n-2, \ldots, 0))
\]

Example 3.4 ([M, §I.2 Ex.3 and §I.3 Ex.1]) Let \( q \) be an indeterminates.

\[
H(t) := \prod_{i=0}^{n-1} \frac{1}{1 - q^i t}
\]

\[
\Rightarrow h_r = \left[ \frac{n + r - 1}{r} \right], \quad e_r = q^{r(r-1)/2}\left[ \frac{n}{r} \right], \quad p_r = \frac{1 - q^{nr}}{1 - q^r}
\]

\[
\left[ \frac{n}{r} \right] := \frac{\prod_{j=1}^{r} (1 - q^{n-j+1})}{\prod_{i=1}^{r} (1 - q^i)} : \text{q-binomial coefficient}
\]

\[
s_\lambda = q^{n(\lambda)} \prod_{x \in \lambda} \frac{1 - q^{n+c(x)}}{1 - q^{h(x)}} \begin{cases}
  c(x) & : \text{content} \\
  h(x) & : \text{hook length} \\
  n(\lambda) & = \sum_{i \geq 1} (i-1) \lambda_i
\end{cases} \quad (\text{See Example 2.4})
\]

Example 3.5 ([M, §I.2 Ex.4 and §I.3 Ex.2]) Let \( n \to \infty \) in Example 3.4.

\[
H(t) := \prod_{i \geq 0} \frac{1}{1 - q^i t}
\]

\[
\Rightarrow h_r = \prod_{i=1}^{r} \frac{1}{1 - q^i}, \quad e_r = q^{r(r-1)/2} h_r, \quad p_r = \frac{1}{1 - q^r}
\]

\[
s_\lambda = q^{n(\lambda)} \prod_{x \in \lambda} \frac{1}{1 - q^{h(x)}}
\]
Example 3.6 ([M, §I.2 Ex.5 and §I.3 Ex.3] and [Andrews, Chap.III])

Let $a$ and $b$ be indeterminates.

$$H(t) := \prod_{i \geq 0} \frac{1 - bq^i t}{1 - aq^i t}$$

$$\Rightarrow h_r = \prod_{i=1}^r \frac{a - bq^{i-1}}{1 - q^i}, \quad e_r = \prod_{i=1}^r \frac{aq^{i-1} - b}{1 - q^i}, \quad p_r = \frac{a^r - b^r}{1 - q^r}$$

$$s_\lambda = q^{n(\lambda)} \prod_{x \in \lambda} \frac{a - bq^{c(x)}}{1 - q^{h(x)}}$$

Proof for the last statement on $s_\lambda$:
Substitute $t \to t/a$ and we have $s_\lambda/a^{\lambda}$ instead of $s_\lambda$. So we can assume $a = 1$. Next, note that the both hand side of the equation to be proved are polynomials in $b$. If $b = q^n$ ($n = 1, 2, \cdots$), it reduces to Example 3.5, hence the equation is valid for infinitely many value of $b$. We are done.

In the above Example 3.6, substitute $a = 1$ and $b = -y$.
For $\sigma = (1, 2, \cdots, r) \in \mathfrak{S}_r$ : cyclic permutation, we have

$$\det(1 - q\sigma | C^r) = 1 - q^r.$$ 

$$\Rightarrow p_r = \frac{1 - (-y)^r}{1 - q^r} = \frac{\det(1 + y\sigma | C^r)}{\det(1 - q\sigma | C^r)}$$

$$\Rightarrow \text{For } w \in \mathfrak{S}_n \text{ with cyclic type } \mu;$$

$$p_\mu = \frac{\det(1 + yw | C^n)}{\det(1 - qw | C^n)} (= \tilde{\tau}(q, y)(w))$$

$$s_\lambda = q^{n(\lambda)} \prod_{x \in \lambda} \frac{1 + yq^{c(x)}}{1 - q^{h(x)}} \text{ (by Example 3.6)}$$

$$= \sum_{\mu} \frac{1}{z_\mu} \chi^\lambda(\mu)p_\mu \text{ (by Theorem 3.2)}$$

$$= \frac{1}{n!} \sum_{w \in \mathfrak{S}_n} \chi^\lambda(w)p_{\mu(w)}(\mu(w) : \text{cyclic type of } w)$$

$$= \frac{1}{n!} \sum_{w \in \mathfrak{S}_n} \chi^\lambda(w)\tilde{\tau}(q, y)(w) \text{ (by the above)}$$

$$= \langle \chi, \tilde{\tau}(q, y) \rangle_{\mathfrak{S}_n} = \tilde{\tau}(\chi; q, y)$$

Mathiew:
\[ \mathcal{H} := \mathbb{C}' \setminus \{ z_i = z_j \} \]
cohomology \[ H^i(\mathcal{H}) : \dim H^i(\mathcal{H}) = \# \{ w \in \mathcal{G} | l'(w) = i \} \]
Is there any relation?
(Cf. Brieskorn [Brieskorn] and Orlik [Orlik].)

Schiffmann:
Is there a formula for \( \kappa(\sigma) \)?

\[ \tau_1(\sigma; q, y) = \prod_{i=1}^{\kappa(\sigma)} (1 + q^i y) \]

partial answer:

\[
\begin{cases}
\text{type } A_{l-1} : & \kappa(\sigma) = l \\
\text{type } E_l & \#(\text{family}) = 3 : \kappa(\sigma) = l - 2
\end{cases}
\]
etc.

Tanisaki:
How about for Hecke algebra \( H_q(W) \)?

\[ L'(\sigma; t) := \sum_{w \in W} \sigma(T_w) t'^{(w)} \]

Oshima:
\( l'(w) \) can be expressed as a linear sum of characters. Is there a closed formula indicating this fact?

partial answer:

\[ c(\chi; t) := \sum_{w \in W} \chi(w) t'^{(w)} \Rightarrow \left. \frac{d}{dt} c(\chi; t) \right|_{t=1} = W \cdot \langle \chi, l' \rangle_W \]

Since \( l'(w) = \sum_{\chi} \langle \chi, l' \rangle_W \chi(w) \), we have

\[ l'(w) = \frac{1}{\# W} \sum_{\chi} \left( \left. \frac{d}{dt} c(\chi; t) \right|_{t=1} \right) \chi(w) = \left. \frac{1}{\# W} \sum_{\chi} c(\chi; t) \chi(w) \right|_{t=1}. \]
